A 38-year-old patient, three children, after the history of previous surgical treatment of chronic disease, was admitted to the Department of Gynecology for acute lower abdominal pain. The patient related the pain, located mainly in the lower right abdomen. The pain was intermittent, not connected with walking, it worsened in lying position and improved in erect position. There were no signs of peritonitis, no fever, no tachycardia — mainly in the evening, which limited the possibility of differential diagnosis with the acute appendicitis. For several months the patient was using hormonal treatment, starting from the gynecological treatment, taking multiple combinations of oral contraceptives and progestogens and finishing on progestogens. During that time a wide range of laboratory examinations and laboratory tests were conducted: the levels of subferritin, C-reactive protein and other biochemical tests were within normal limits. The ultrasound and the CT scan showed no significant pathological abnormalities and CT scan of abdomen and pelvis was normal. During gynecological examination and the history was related, there was no endometriosis and no adenomyosis. The patient was offered different therapies — including hormonal, physical, and surgical, but none of them brought any relief. In the end, the patient was diagnosed with pelvic congestion syndrome and after the treatment of this condition, the symptoms and signs were relieved.

Pelvic congestion syndrome (PCS) is a poorly understood and frequently misdiagnosed disorder of the pelvic venous circulation. It is defined as a condition of the pelvic venous system, characterized by the chronic congestion of the pelvic veins in the presence of chronic pelvic pain. The pathogenesis of PCS is still unclear, but it is thought to be related to the presence of pelvic varicose veins. The pain is usually described as a dull, aching pain, which is worse in the evening and in the morning. The pain is usually located in the lower abdomen and is often associated with a feeling of heaviness in the pelvic region. The diagnosis of PCS is based on the history and physical examination. The treatment of PCS is usually conservative, but in some cases, surgical treatment may be necessary.
